

## Zoom Lens and Photographing System

### BACKGROUND OF THE INVENTION

#### Field of the Invention

5           The present invention relates to a zoom lens  
suitable for a TV camera, video camera, and the like.

#### Related Background Art

As an autofocus (AF) system in a video camera or  
the like, a system called "hill-climbing AF" which  
10 obtains the distance to a principal object and drives a  
focus unit to an appropriate position is widely used.

In this system, the direction of the best imaging  
position is detected from a change in a video signal by  
using some of the lens units of an image pickup system  
15 for imaging, and the extension direction of a focusing  
lens is calculated. A merit of this system is that no  
optical system need be newly used for distance  
measurement.

In addition, in this system, in order to check  
20 whether the best imaging position is located before or  
after the image pickup surface (CCD surface or film  
surface), a partial optical system of the image pickup  
system is slightly amplitude-driven (to be referred to  
as wobbled hereinafter) in the optical axis direction.  
25 A focus unit is driven to set the best focus on the  
image pickup surface on the basis of the detected  
signal.

At this time, since part of the optical system is wobbled, the imaging magnification greatly changes to result in poor screen display unless lens units and the like are properly arranged.

5           As a method of reducing a change in imaging magnification, the method disclosed in Japanese Patent No. 2744336 is available. This method is associated with a rear focus zoom lens which has the first unit having a positive refractive power, the second unit  
10           having a negative refractive power for magnification changing operation, the third unit having a positive refractive power, and the fourth unit having a positive refractive power and serving to correct an image plane fluctuation with a change in magnification, and is  
15           designed to perform focusing by using the fourth unit.

          A change in imaging magnification accompanying wobbling can be expressed by a paraxial trace. Several conditions for suppressing a change in imaging magnification accompanying wobbling small are described  
20           in USP 5,138,492.

          These conditions are, however, insufficient to be applied to an image pickup system which has a wobbling lens unit placed in a relay lens unit located closer to the image side than the stop and allows  
25           insertion/removal of an extender for shifting the focal length to the telephoto side.

          More specifically, the conditions described in the

10032767 122701

above reference are effective for a method of reducing a change in imaging magnification in a state where an optical arrangement behind the stop is fixed, but are not sufficient to be applied to a case wherein the arrangement of an optical system is changed upon insertion/removal of an extender or the like and the incident angle of an off-axis principal ray on a wobbling lens unit, in particular, changes.

10 SUMMARY OF THE INVENTION

It is an object of the present invention to provide a 4-unit zoom lens which exhibits a small change in imaging magnification accompanying wobbling even with insertion of an optical system such as an extender in the fourth unit serving as a relay lens unit and also exhibits excellent optical performance throughout the entire magnification change range.

In order to achieve the above object, according to the present invention, in a zoom lens in/from which a magnification changing optical unit for changing an overall focal length of the zoom lens can be inserted/removed, a wobbling unit which can be slightly amplitude-driven in an optical axis direction to detect a best imaging position is placed closer to an image side than an insertion position of the magnification changing optical unit.

With this arrangement, a change in imaging

magnification caused when the wobbling unit is slightly driven in the optical axis direction can be reduced regardless of insertion/removal of the magnification changing optical unit.

5           The zoom lens sequentially includes, from an object side, a first unit which is fixed in magnification changing operation and has a positive refractive power, a second unit which moves in the optical axis direction in magnification changing  
10 operation and has a negative refractive power, a third unit for correcting an image plane fluctuation accompanying magnification changing operation, and a fourth unit having a positive refractive power for imaging, and a magnification changing optical unit  
15 which changes the overall focal length of the zoom lens can be inserted/removed in/from the fourth unit. In this zoom lens, a wobbling unit which can be slightly amplitude-driven in the optical axis direction to detect a best imaging position is placed closer to the  
20 image side than the insertion position of the magnification changing optical unit, and a stop for adjustment of light amount is preferably disposed at the object side with respect to the fourth unit.

          More specifically, for example, when the wobbling  
25 unit is placed in the fourth unit and amplitude-driven to make an amplitude halfwidth of a backfocus change amount become  $1/2$  a depth of focus,

$$|\alpha_1(S_1 - E_1)/fw_1| < 0.6 \quad \dots(1)$$

is satisfied, where  $\alpha_1$  is an angle of an off-axis sub-principal ray incident on an object-side principal plane of the wobbling unit (without insertion of the magnification changing optical unit),  $S_1$  is a distance to a stop viewed from the object-side principal plane of the wobbling unit (without insertion of the magnification changing optical unit),  $E_1$  is a distance to an image pickup plane viewed from an image-side principal plane of the wobbling unit (without insertion of the magnification changing optical unit), and  $fw_1$  is a focal length at a wide-angle end without insertion of the magnification changing optical unit.

With this arrangement, a change in imaging magnification accompanying wobbling without insertion of the magnification changing optical unit can be suppressed sufficiently small.

In addition, when the wobbling unit is placed in the fourth unit amplitude-driven to make an amplitude halfwidth of a backfocus change amount become  $1/2$  a depth of focus,

$$|\alpha_2(S_2 - E_2)/fw_2| < 2.2 \quad \dots(2)$$

is satisfied, where  $\alpha_2$  is an angle of an off-axis sub-principal ray incident on the object-side principal plane of the wobbling unit (with insertion of the magnification changing optical unit),  $S_2$  is a distance to the stop viewed from the object-side principal plane

of the wobbling unit (with insertion of the magnification changing optical unit), E2 is a distance to the image pickup plane viewed from the image-side principal plane of the wobbling unit (with insertion of the magnification changing optical unit), and fw2 is a focal length at the wide-angle end with insertion of the magnification changing optical unit.

In addition, in the fourth unit,

$$-0.001 < \phi / I_m < 0.0015 \quad \dots(3)$$

is satisfied, where  $\phi$  is a refractive power of a lens unit located immediately before the wobbling unit in the fourth unit, and  $I_m$  is an image size of an image pickup element.

With this arrangement, a change in incident angle on the wobbling unit upon insertion/removal of the magnification changing optical unit can be made small. This makes it possible to reduce a change in imaging magnification more reliably.

Further, the amplitude halfwidth of the wobbling unit before/after insertion of the magnification changing optical system is preferably so set as to satisfy the following condition (4).

$$\Delta x_2 = F \cdot \Delta x_1 \quad \dots\dots(4)$$

where  $\Delta x_1$  is an amplitude halfwidth of the wobbling unit before insertion of the magnification changing optical system,  $\Delta x_2$  is an amplitude halfwidth of the wobbling unit after insertion of the

magnification changing optical system, and  $F$  is a rate of change of  $F$ -number due to insertion/removal of the magnification changing optical system.

Note that a reduction in the size and weight of the wobbling unit to be slightly amplitude-driven may be attained by placing the wobbling unit closest to the image side in the fourth unit.

If this system is designed to retract part of the fourth unit from the optical axis by inserting the magnification changing optical unit, a large space for the insertion of the magnification changing optical unit can be ensured while a reduction in the overall size of the zoom lens is attained. This makes it possible to suppress a deterioration in optical performance at the time of insertion of the magnification changing optical unit.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS (First Embodiment)

Figs. 1 to 6 show the cross-sectional configurations of lenses, of zoom lenses according to the first embodiment of the present invention, which are located at the wide-angle end and infinity focus position in the first to sixth numerical embodiments.

20

Referring to Figs. 1 to 6, a first unit (front element) I has a positive refractive power, and a variator II serves as the second unit having a negative refractive power and capable of moving in the optical axis direction in magnification changing operation.

25

The second unit II is monotonously moved to the image side on the optical axis to change the magnification from the wide-angle end to the telephoto end. In magnification changing operation, the second unit II is moved within a range including an imaging magnification of  $1\times$  ( $-1\times$ ) (i.e. equal magnification).

A compensator III serves as the third unit which can move in the optical axis direction to correct an image plane fluctuation accompanying magnification changing operation.

A stop SP is used for light amount adjustment. A fourth unit IV having a positive refractive power is used for imaging.

A glass block G is a color separation prism, optical filter, or the like. A wobbling unit wo can be slightly amplitude-driven in the optical axis direction to detect the best imaging position. A lens unit L4b is placed immediately before the wobbling unit in the fourth unit.

An extender (magnification changing optical unit) EX for increasing or decreasing the overall focal length of the zoom lens system can be inserted/removed (or mounted/dismounted) in/from the space in the fourth unit.

In this embodiment, the configuration of a lens unit (to be referred to as a relay unit hereinafter) located closer to the image side than the stop SP is

properly set such that a change in imaging magnification accompanying wobbling of the wobbling unit  $w_o$  is reduced regardless of whether the extender EX is inserted/removed.

5       The wobbling unit  $w_o$  needs to be amplitude-driven at high speed in the optical axis direction. It is therefore preferable that the wobbling unit  $w_o$  have a proper backfocus sensitivity degree and be light in weight. A zoom lens for a TV set needs to have a long  
10       backfocus and a small F-number, and hence requires many lenses constituting each unit. In addition, each lens has a large effective diameter, and an extender, macro photographing mechanism, flange-back adjustment  
15       mechanism, and the like must be arranged in the relay unit, resulting in a low degree of freedom in placing the wobbling unit.

      Figs. 7 and 8 schematically show lens units behind the stop SP. Fig. 7 shows a state where the extender EX is not inserted. Fig. 8 shows a state where the  
20       extender EX is inserted. Referring to Fig. 8, the magnification of the extender EX is set to  $2\times$ , and an image is enlarged by  $2\times$  on an image plane.

      Referring to Fig. 7, an image height change ratio can be expressed as follows. Letting  $\alpha_1$  be the  
25       incident angle of sub-principal ray on the wobbling unit  $w_o$ ,  $\phi_{w_o}$  be the power of the wobbling unit  $w_o$ ,  $S_1$  be the distance between the wobbling unit  $w_o$  and an

image plane,  $\phi_{4c}$  be the power of lens unit L4c located closer to the image side than the wobbling unit wo,  $\Delta x$  be the wobbling amount,  $(S_1 - E_1)$  be the difference between the distance to a virtual image of the stop SP viewed from the wobbling unit wo and the distance to a virtual image of the image plane viewed from the wobbling unit wo, and  $\Delta y$  be the image height change amount at the time of wobbling, an image height change ratio  $\Delta y/f_w$  (where  $f_w$  is the focal length of the overall system at the wide-angle end) can be expressed by

$$\frac{\Delta y}{f_w} = \alpha_1 \cdot \phi_{wo} \cdot (S_1 \phi_{4c} - 1) \cdot \Delta x \cdot \{\Delta x - (S_1 - E_1)\} \cdot \frac{1}{f_w}$$

The wobbling amount  $\Delta x$  is a sufficiently small value relative to  $(S_1 - E_1)$ , and hence can be expressed by

$$\frac{\Delta y}{f_w} = \alpha_1 \cdot (S_1 \phi_{4c} - 1) \cdot (S_1 - E_1) \cdot \frac{1}{f_w}$$

In the configuration of the zoom lens according to this embodiment, parameters that change upon insertion/removal of the extender EX and have great influences on the image height change ratio  $\Delta y/f_w$  are the incident angle  $\alpha_1$  of a principal ray on the wobbling unit wo and  $(S_1 - E_1)$ .

The allowable value of the wobbling amount  $\Delta x$  will be described. It is said that the resolution of the visual sense of a person having 20/20 vision is about

10032767-12704

one minute. If, for example, the person watches a  
30-inch TV screen (having a screen size of about 50 cm  
in the horizontal direction) at a distance of 2.5 m,  
the viewing angle in the horizontal direction becomes  
5 about 680 minutes. A resolution of one minute  
therefore corresponds to 0.15% of the screen.

If the lens is stopped down, the depth of focus  
increases as compared with that at full aperture. In  
addition, a larger wobbling amount is required to  
10 detect the best focus position, and hence the image  
height change ratio increases.

In consideration of the fact that the highest  
frequency in use of an F-number range is about full  
aperture: F/5.6, an image height change ratio is  
15 allowed at most 0.15% at F/5.6. An allowable value at  
full aperture (F/1.752) becomes about 0.06% which is  
about 1/3 the image height change ratio at F/5.6. The  
upper limit of conditional expression (1) is determined  
such that the image height change ratio at full  
20 aperture (F/1.752) falls within an image height change  
ratio of 0.06% (0.15% at F/5.6), and falls within the  
allowable range even if the image height change ratio  
changes upon insertion of the extender EX.

The relationship between the wobbling amount  $\Delta x$   
25 and the change amount in backfocus  $\Delta sk$  is expressed by

$$\Delta x = \frac{\Delta sk}{(1 - \beta_1^2) \cdot \beta_2^2}$$

where  $\beta_1$  is a lateral magnification of the wobbling unit, and  $\beta_2$  is a lateral magnification of an optical system placed at the image side with respect to the wobbling unit. When the change amount in backfocus  $\Delta sk$  is 1/2 the depth of focus, the relationship between the change amount in backfocus  $\Delta sk$  and the F-number  $fno$  is expressed by

$$\Delta sk = \delta \cdot fno / 2$$

where  $\delta$  is a permissible circle of confusion determined by the camera system.

In the present invention, the wobbling lens unit is disposed closer to the image side than the magnification changing optical unit capable of being inserted and removed, so that the wobbling amount  $\Delta x$  has a relation proportional to the F-number since both  $\beta_1$  and  $\beta_2$  are constant before/after insertion of the magnification changing optical system.

Considering the wobbling amount after insertion of a 2x extender, since the F-number becomes doubled, the depth of focus also becomes doubled. The amplitude driving amount of the wobbling unit must also be doubled.

The F-number in practical use at the time of insertion of the 2x extender falls within a narrow range of about F/4 to F/5.6 because the F-number at the full aperture end increases. For this reason, if a maximum of 0.15% of the value at F/5.6 is allowed at

the time of insertion of the extender, the allowable amount at full aperture ( $F/4$ ) becomes about 0.1%. That is, an allowable amount as large as double the value before the insertion of the extender can be allowed.

5           The allowable upper limit value of an image height change ratio indicated by conditional expressions (1) and (2) is the value set when the wobbling unit is amplitude-driven in the optical axis direction such that the amplitude halfwidth of a change in backfocus  
10 becomes  $1/2$  the depth of focus. In practice, this value changes depending on the manner of determining a wobbling amount with respect to the depth of focus (e.g., setting the amplitude halfwidth to  $1/3$  the depth of focus or to be equal to it), an assumed screen size,  
15 and the like.

          Considering a system frequency using F-numbers equal to or larger than  $F/5.6$  or setting of smaller full aperture F-numbers, a system is required in which the image height change ratio at full aperture is  
20 further suppressed and a change before/after insertion of an extender is smaller.

          Consider only a state where no extender is inserted. In this case, to reduce a change in imaging magnification accompanying wobbling, the incident angle  
25  $\alpha_1$  of a sub-principal ray on the wobbling unit and the difference ( $S_1 - E_1$ ) between the distance  $E_1$  to the stop viewed from the wobbling unit and the distance  $S_1$

100-23-2200

to the image plane viewed from the wobbling unit must be reduced.

When the extender EX in the state shown in Fig. 7 is inserted (Fig. 8), the incident angle of sub-principal ray on the wobbling unit  $w_0$  changes to  $\alpha_2$ , and a distance E2 to the stop SP viewed from the wobbling unit  $w_0$  changes. However, a distance S2 to the image plane viewed from the wobbling unit  $w_0$  is almost constant ( $S_2 \approx S_1$ ) regardless of insertion/removal of the extender, and hence a change in imaging magnification at the time of insertion of the extender remains.

In order to reduce a change in imaging magnification accompanying wobbling in a state where the extender is not inserted, the following condition must be satisfied:

$$0.05 < |\alpha_1 (S_1 - E_1)/f_{w1}| < 0.6 \quad \dots(1)$$

With approach to the lower limit value of conditional expression (1), a change in imaging magnification while the extender is not inserted is reduced, and an ideal condition is obtained.

While the extender is inserted, it is difficult to cancel out the distance E2 with respect to the distance S2 in Fig. 8, and a change in imaging magnification remains. This condition is not necessarily a desired condition for an optical system in/from which the extender is inserted/removed.

If the upper limit value is exceeded, a change in imaging magnification without insertion of the extender is large. It indicates that this condition is not suitable for wobbling.

5           Therefore, while the extender is inserted, the following is preferably satisfied:

$$0.05 < |\alpha_2(S_2 - E_2)/f_{w2}| < 2.2 \quad \dots(2)$$

10           If the upper limit value of this conditional expression (2) is exceeded, it indicates that a change in imaging magnification at the time of insertion/removal of the extender is large.

In addition, the refractive power  $\phi_{4b}$  of the lens unit L4b located immediately before the wobbling unit wo in the fourth unit IV preferably satisfies

15            $-0.001 < \phi_{4b}/l_m < 0.0015 \quad \dots(3)$

where  $l_m$  is the image size of the image pickup element.

20           If the positive or negative refractive power of the lens unit L4b is increased beyond the range of conditional expression (3), the incident angle of a principal ray on the wobbling unit wo greatly changes from  $\alpha_1$  to  $\alpha_2$  or from  $\alpha_2$  to  $\alpha_1$ , and a change in imaging magnification becomes large under one of the conditions.

25           It is preferable to set the amplitude amount of the wobbling unit to the following condition (4) before/after insertion of the magnification changing optical system.

10032757-42204

$$\Delta x_2 = F \cdot \Delta x_1 \quad \dots\dots(4)$$

where  $\Delta x_1$  is an amplitude halfwidth of the wobbling unit before insertion of the magnification changing optical system,  $\Delta x_2$  is an amplitude halfwidth of the wobbling unit after insertion of the magnification changing optical system, and F is a rate of change of F-number due to insertion/removal of the magnification changing optical system. This enables the best focus position to be detected and a system in which blur is not conspicuous on a screen upon detection to be provided irrespective of whether the magnification changing optical system is inserted or not.

<<Numerical Embodiments>>

The numerical embodiments of this embodiment will be described below. In the numerical embodiments 5 to 6, let  $r_i$  be the radius of curvature of the  $i$ th lens from the object side,  $d_i$  be the thickness or air gap of the  $i$ th optical member from the object side, and  $n_i$  and  $\gamma_i$  ("v<sub>i</sub>" in the tables) be the refractive index and Abbe number, respectively, of the glass of the  $i$ th lens from the object side with respect to a d line.

Letting the X-axis be the optical axis direction, the H-axis be a direction perpendicular to the optical axis, a traveling direction of light be positive, R be the paraxial radius of curvature, and B, C, D, and E be aspherical coefficients, an aspherical shape is expressed by

10032767 122701

$$X = \frac{(1/R) H^2}{1 + \sqrt{1 - (H/R)^2}} + BH^4 + CH^6 + DH^8 + EH^{10}$$

100326 12201

In the numerical embodiment 1 shown in Fig. 1, to reduce variations in optical performance upon insertion of the extender EX, the extender EX is preferably placed in a substantially afocal parallel light beam.

5 In addition, a wide gap is required to satisfy the extender magnification requirement and optical performance requirement.

As a wobbling unit which satisfies conditional expression (1), has a proper backfocus sensitivity degree accompanying slight amplitude driving of the wobbling unit  $w_0$ , and exhibits a small change in imaging magnification, all or some of lens units located closer to the image side than the extender EX are preferably used.

10 In the numerical embodiment 1, three lenses of which form two units in the fourth unit and are located closest to the image side, are used as wobbling unit lenses. By making some lenses of the fourth unit movable, a reduction in the weight of the wobbling unit  $w_0$  is achieved. In addition, by setting the refractive power of the lens unit L4b located immediately before the wobbling unit within the range of conditional expression (3), a change in imaging magnification is small regardless of the presence/absence of the  
20 extender EX.  
25

In the numerical embodiment 1, the extender EX can be inserted/removed in/from a space with gap  $d_{26} = 36$

mm.

Table 12 shows the numerical values of conditional expressions and imaging magnification change ratios in the respective numerical embodiments. Each imaging magnification change ratio is the value obtained when wobbling is performed upon setting the amplitude halfwidth to 1/2 the depth of focus at the full aperture end.

If, for example, the permissible circle of  
10 confusion of a 2/3-inch CCD (image size:  $\phi 11$  mm) which  
is the mainstream in TV cameras is set to about 0.021  
mm, the depth of focus at F/2 becomes about 0.04 mm.

Figs. 9 and 10 are aberration diagrams at the wide-angle end and telephoto end without insertion of the extender in the first numerical embodiment.

Fig. 19 is an aberration diagram at the wide-angle end with insertion of the extender.

10032767-122701

In the numerical embodiment 2 shown in Fig. 2, the second lens located closer to the image side than the insertion gap of the extender EX is used as a wobbling unit lens. The extender EX can be inserted/removed  
5 in/from a space with  $d_{24} = 30$  mm.

Since the positive refractive power  $\phi_{4b}$  of the lens unit L4b located immediately before the wobbling unit  $w_o$  is brought near to the upper limit in the numerical embodiment 1, a change (conditional  
10 expression (2)) in imaging magnification upon insertion/removal of the extender takes a large value.

The lens unit L4c constituted by six lenses which form four units in the fourth unit and are located closer to the image side than the wobbling unit  $w_o$  are  
15 constituted by two lens units L4c1 and L4c2. In addition, the use of the lens unit L4c2 allows macro photographing for proximity photographing and flange-back adjustment for adjusting the dimensional error between the reference surface of a lens (flange  
20 surface) and an image plane in a lens-interchangeable camera, independently of the main focusing lens.

Figs. 11 and 12 are aberration diagrams at the wide-angle end and telephoto end without insertion of the extender in the numerical embodiment 1. Fig. 20 is  
25 an aberration diagram at the wide-angle end with insertion of the extender.

10032767.12201

In contrast to the lens system in the numerical embodiment 2, in the numerical embodiment 3 shown in Fig. 3, the extender can be inserted in the space with d24 to d26 by retracting (ejecting) part (L4b) of the fourth unit from the optical axis at the time of insertion of the extender EX. By retracting part of the fourth unit, a reduction in the space for insertion/removal of the extender can be attained. This makes it possible to achieve a reduction in the size of the lens system and suppress a deterioration in optical performance at the time of insertion of the extender by effectively using the wide space.

Even in a case where part of the fourth unit is retracted at the time of insertion of the extender, an appropriate imaging magnification change ratio can be kept by properly setting the refractive power of the lens unit L4b.

Fig. 21 is an aberration diagram at the wide-angle end at the time of insertion of the extender in the numerical embodiment 3.

In the numerical embodiment 4 shown in Fig. 4, the second lens located closer to the image side than the insertion gap for the extender EX is used as a wobbling unit lens. In addition, the extender EX can be  
5 inserted in a space with  $d_{26} = 30$  mm.

In the numerical embodiment 4, the lens unit L4b located closer to the object side than the wobbling unit wo has a negative refractive power. In contrast to the numerical embodiment 1, since  $\phi_{4b}$  is brought  
10 closer to the lower limit, a change in imaging magnification (conditional expression (2)) accompanying insertion of the extender EX takes a large value.

Figs. 13 and 14 are aberration diagrams at the wide-angle end and telephoto end without insertion of  
15 the extender in the numerical embodiment 4. Fig. 22 is an aberration diagram at the wide-angle end with insertion of the extender.

In the numerical embodiment 5 shown in Fig. 5, the second lens located closer to the image side than the insertion gap for the extender EX is used as a wobbling unit lens, and the extender EX can be inserted/removed in/from a space with  $d_{24} = 30$  mm. In the numerical embodiment 5, the wobbling unit wo has a negative refractive power.

In the numerical embodiment 5,  $\phi 4b$  is brought closer to the upper limit, a change in imaging magnification (conditional expression (2)) accompanying insertion/removal of the extender takes a large value.

In this numerical embodiment, the unit L4c is integrally moved to allow macro photographing and flange-back adjustment.

Figs. 15 and 16 are aberration diagrams at the wide-angle end and telephoto end without insertion of the extender in the numerical embodiment 5. Fig. 23 is an aberration diagram at the wide-angle end with insertion of the extender.

100326 12201

In the numerical embodiment 6 shown in Fig. 6, the sixth lens of the fourth unit from the image side is used as a wobbling unit lens, and the extender EX can be inserted/removed in/from a space with  $d_{34} = 45.2$  mm.

5 In the numerical embodiment 6, unlike in the numerical embodiments 1 to 5, an optical system is placed in the space in the fourth unit, in/from which the extender EX is inserted/removed, instead of setting a large space as an air gap at the time of 1x, and the  
10 optical system at the time of 1x is retracted (ejected) from the optical axis upon insertion of the extender.

In this case as well, by setting the refractive power of the lens unit L4b within an appropriate range, an image height change ratio can be suppressed low  
15 regardless of the insertion/removal of the extender EX.

In each numerical embodiment described above, the lens units located closer to the object side than the extender EX are fixed regardless of insertion/removal of the extender EX. By placing an optical system at  
20 the time of 1x and insertion of the extender, the degree of freedom in design increases, and high optical performance with a low image height change ratio can be realized.

Figs. 17 and 18 are aberration diagrams at the  
25 wide-angle end and telephoto end without insertion of the extender in the numerical embodiment 6. Fig. 24 is an aberration diagram at the wide-angle end with insertion the extender.

TABLE 12

As described above, according to this embodiment, there is provided a zoom lens suitable for a TV camera, video camera, or the like, which has a large aperture of an F-number of about 1.8 to 2 and a high magnification ratio of 10x or more, exhibits a small change in imaging magnification accompanying wobbling regardless of insertion/removal of an optical system such as the extender EX in the relay unit, and has excellent optical performance throughout the entire magnification change range.

(Second Embodiment)

A photographing system (TV camera system) using one of the zoom lenses in the numerical embodiments 1 to 6 as a photographing optical system will be described next with reference to Fig. 25.

Referring to Fig. 25, this photographing system includes a photographing system body 106 including lenses, a photographing optical system 101 formed by one of the zoom lenses in the numerical embodiments 1 to 6, a glass block 102 corresponding to a filter or color separation prism, an image pickup element 103 such as a CCD for receiving an object image formed by the photographing optical system 101, and CPUs 104 and 105 for controlling the photographing system and lenses.

By using one of the zoom lenses in the numerical embodiments 1 to 6 for a photographing system such as a

TV camera, a photographing system can be realized, in which a change in imaging magnification upon slight amplitude driving of a wobbling unit  $w_0$  in the optical axis direction for autofocus operation is small

5 regardless of whether an extender EX is inserted/removed, i.e., poor screen display can be prevented.

10 The present invention is not limited to the zoom lenses shown in Figs. 1 to 6. A lens unit other than the lens units shown in Figs. 1 to 6 may be added to the zoom lens.

15 For example, as shown in Fig. 26, the lens unit may be constituted by I, II, III, IV, and V units. The same reference numerals as in Fig. 26 denote the same parts in Fig. 25.

20 As has been described above, according to the present invention, a change in imaging magnification caused when the wobbling unit is slightly amplitude-driven in the optical axis direction can be suppressed small regardless of the insertion/removal of the magnification changing optical unit.

25 Note that if conditional expression (1) is satisfied, a change in imaging magnification accompanying wobbling without insertion of the magnification changing optical unit can be sufficiently suppressed small.

If conditional expression (2) is satisfied, a

change in imaging magnification accompanying wobbling with insertion of the magnification changing optical unit can be sufficiently suppressed small.

5 If conditional expression (3) is satisfied, a change in incident angle on the wobbling unit upon insertion/removal of the magnification changing optical unit can be made small. This makes it possible to reduce a change in imaging magnification more reliably.

10 Note that if the wobbling unit is placed closest to the image side in the fourth unit, a reduction in the size and weight of the wobbling unit to be slightly amplitude-driven can be attained.

15 If this system is designed to retract part of the fourth unit from the optical axis by inserting the magnification changing optical unit, a large space for the insertion of the magnification changing optical unit can be ensured while a reduction in the overall size of the zoom lens is attained. This makes it possible to suppress a deterioration in optical  
20 performance at the time of insertion of the magnification changing optical unit.
